Syntax

- Redirecting stdout to out can also be obtained in two ways:
 - cmd >out
 - cmd 1>out
- Redirecting stdout and stderr to out and err respectively: cmd >out 2>err .
- Redirecting stdout and stderr to all_output : cmd >all_output 2>&1 .
- Redirecting stdin from the shell to a file named input_file :
 - cmd 0<input_file
 - cmd <input_file
- Using tr to replace x with 3 (input implied): tr x 3

Concepts

- A **process** is a running instance of a command.
- Standard streams are certain communication channels through which processes communicate with the computer.
- There are three standard streams:
 - Standard input (stdin)
 - Standard output (stdout)
 - Standard error (stderr)
- Regular output uses stdout, where as error messages come through stderr
- The computer sees standard streams as non-negative integers called file descriptors:

File Descriptor	Stream	Full name
0	stdin	Standard input
1	stdout	Standard output
2	stderr	Standard error

- The order of redirection matters. The following two commands do different things:
 - cmd 2>&1 >filename
 - cmd >filename 2>&1
- Many commands take input not only from the filenames that are passed as arguments to them, but also from standard input.
